27	Abstract	
28 29 30 31	This document is one of a set of documents, which together describe all aspects of a new Interne an application level protocol that can be used for distributed printing using Internet tools and tedefines the rules for encoding IPP operations and IPP attributes into a new Internet mime media. This document also defines the rules for transporting over HTTP a message body whose Content.	chnologies. This document type called "application/ipp".

- 32 The full set of IPP documents includes:
- Design Goals for an Internet Printing Protocol [ipp-req]
- Rationale for the Structure and Model and Protocol for the Internet Printing Protocol [ipp-rat]
- 35 Internet Printing Protocol/1.1: Model and Semantics [ipp-mod]
- Internet Printing Protocol/1.1: Encoding and Transport (this document)
- 37 Internet Printing Protocol/1.1: Implementer's Guide [ipp-iig]
- Mapping between LPD and IPP Protocols [ipp-lpd]
- 39 The document, "Design Goals for an Internet Printing Protocol", takes a broad look at distributed printing functionality, and it
- 40 enumerates real-life scenarios that help to clarify the features that need to be included in a printing protocol for the Internet. It
- 41 identifies requirements for three types of users: end users, operators, and administrators. It calls out a subset of end user
- requirements that are satisfied in IPP/1.1. Operator and administrator requirements are out of scope for version 1.1.
- The document, "Rationale for the Structure and Model and Protocol for the Internet Printing Protocol", describes IPP from a
- 44 high level view, defines a roadmap for the various documents that form the suite of IPP specifications, and gives background
- and rationale for the IETF working group's major decisions.
- The document, "Internet Printing Protocol/1.1: Model and Semantics", describes a simplified model with abstract objects, their
- 47 attributes, and their operations that are independent of encoding and transport. It introduces a Printer and a Job object. The Job
- object optionally supports multiple documents per Job. It also addresses security, internationalization, and directory issues.
- 49 This document "Internet Printing Protocol/1.1: Implementer's Guide", gives advice to implementers of IPP clients and IPP
- 50 objects.
- 51 The document "Mapping between LPD and IPP Protocols" gives some advice to implementers of gateways between IPP and
- 52 LPD (Line Printer Daemon) implementations.

## 1. Introduction

- This document contains the rules for encoding IPP operations and describes two layers: the transport layer and the operation
- 95 layer
- The transport layer consists of an HTTP/1.1 request or response. RFC 2068 [rfc2068] describes HTTP/1.1. This document
- 97 specifies the HTTP headers that an IPP implementation supports.
- 98 The operation layer consists of a message body in an HTTP request or response. The document "Internet Printing
- 99 Protocol/1.1: Model and Semantics" [ipp-mod] defines the semantics of such a message body and the supported values. This
- document specifies the encoding of an IPP operation. The aforementioned document [ipp-mod] is henceforth referred to as the
- 101 "IPP model document"

# 2. Conformance Terminology

- The key words "MUST", "MUST NOT", "REQUIRED", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and
- "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [rfc2119].

# 3. Encoding of the Operation Layer

- The operation layer MUST contain a single operation request or operation response. Each request or response consists of a
- sequence of values and attribute groups. Attribute groups consist of a sequence of attributes each of which is a name and value.
- Names and values are ultimately sequences of octets
- The encoding consists of octets as the most primitive type. There are several types built from octets, but three important types
- are integers, character strings and octet strings, on which most other data types are built. Every character string in this
- encoding MUST be a sequence of characters where the characters are associated with some charset and some natural language.
- A character string MUST be in "reading order" with the first character in the value (according to reading order) being the first
- character in the encoding. A character string whose associated charset is US-ASCII whose associated natural language is US
- English is henceforth called a US-ASCII-STRING. A character string whose associated charset and natural language are
- specified in a request or response as described in the model document is henceforth called a LOCALIZED-STRING. An octet
- string MUST be in "IPP model document order" with the first octet in the value (according to the IPP model document order)
- being the first octet in the encoding Every integer in this encoding MUST be encoded as a signed integer using two's-
- 118 complement binary encoding with big-endian format (also known as "network order" and "most significant byte first"). The
- number of octets for an integer MUST be 1, 2 or 4, depending on usage in the protocol. Such one-octet integers, henceforth
- called SIGNED-BYTE, are used for the version-number and tag fields. Such two-byte integers, henceforth called SIGNED-
- 121 SHORT are used for the operation-id, status-code and length fields. Four byte integers, henceforth called SIGNED-INTEGER,
- are used for values fields and the sequence number.
- The following two sections present the operation layer in two ways
  - informally through pictures and description
  - formally through Augmented Backus-Naur Form (ABNF), as specified by RFC 2234 [rfc2234]

#### 3.1 Picture of the Encoding

The encoding for an operation request or response consists of:

146

147

148

149

153

154155

156

157

158

128			
129 130	version-number	2 bytes	- required
131 132 133	operation-id (request) or status-code (response)	2 bytes	- required
134 135	request-id	4 bytes	- required
136 137 138	xxx-attributes-tag	1 byte	-0 or more
139	xxx-attribute-sequence	n bytes	-0 or more
140 141 142	end-of-attributes-tag	1 byte	- required
142 143 144	data	q bytes	- optional
177			

The xxx-attributes-tag and xxx-attribute-sequence represents four different values of "xxx", namely, operation, job, printer and unsupported. The xxx-attributes-tag and an xxx-attribute-sequence represent attribute groups in the model document. The xxx-attributes-tag identifies the attribute group and the xxx-attribute-sequence contains the attributes.

- The expected sequence of xxx-attributes-tag and xxx-attribute-sequence is specified in the IPP model document for each operation request and operation response.
- A request or response SHOULD contain each xxx-attributes-tag defined for that request or response even if there are no attributes except for the unsupported-attributes-tag which SHOULD be present only if the unsupported-attribute-sequence is non-empty. A receiver of a request MUST be able to process as equivalent empty attribute groups:
  - a) an xxx-attributes-tag with an empty xxx-attribute-sequence,
  - b) an expected but missing xxx-attributes-tag.

The data is omitted from some operations, but the end-of-attributes-tag is present even when the data is omitted. Note, the xxx-attributes-tags and end-of-attributes-tag are called 'delimiter-tags'. Note: the xxx-attribute-sequence, shown above may consist of 0 bytes, according to the rule below.

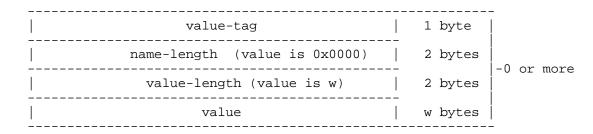

An xxx-attributes-sequence consists of zero or more compound-attributes.

159		-
160	compound-attribute	s bytes - 0 or more
161		· =

- A compound-attribute consists of an attribute with a single value followed by zero or more additional values.
- Note: a 'compound-attribute' represents a single attribute in the model document. The 'additional value' syntax is for attributes with 2 or more values.
- 165 Each attribute consists of:

166			
167	value-tag		1 byte
168 169 170	name-length (value is u)		2 bytes
170 171 172	name		u bytes
172 173 174	value-length (value is v)		2 bytes
174 175 176	value		v bytes
1/0			

An additional value consists of:

Note: an additional value is like an attribute whose name-length is 0.

From the standpoint of a parsing loop, the encoding consists of:

version-number	2 bytes	- required
operation-id (request) or status-code (response)	2 bytes	- required
request-id	4 bytes	- required
tag (delimiter-tag or value-tag)	1 byte	  -0 or more
empty or rest of attribute	x bytes	
end-of-attributes-tag	2 bytes	- required
data	y bytes	- optional

The value of the tag determines whether the bytes following the tag are:

- attributes
  - data
- the remainder of a single attribute where the tag specifies the type of the value.

213

The syntax below is ABNF [rfc2234] except 'strings of literals' MUST be case sensitive. For example 'a' means lower case 'a'

#### 3.2 Syntax of Encoding

OCTET-STRING = \*BYTE

260 261

and not upper case 'A'. In addition, SIGNED-BYTE and SIGNED-SHORT fields are represented as '%x' values which show 214 their range of values. 215 216 ipp-message = ipp-request / ipp-response ipp-request = version-number operation-id request-id 217 \*(xxx-attributes-tag xxx-attribute-sequence) end-of-attributes-tag data 218 ipp-response = version-number status-code request-id 219 \*(xxx-attributes-tag xxx-attribute-sequence) end-of-attributes-tag data 220 xxx-attribute-sequence = \*compound-attribute 221 222 xxx-attributes-tag = operation-attributes-tag / job-attributes-tag / 223 printer-attributes-tag / unsupported-attributes-tag 224 225 version-number = major-version-number minor-version-number 226 major-version-number = SIGNED-BYTE; initially %d1 227 minor-version-number = SIGNED-BYTE; initially %d0 228 229 operation-id = SIGNED-SHORT ; mapping from model defined below 230 status-code = SIGNED-SHORT; mapping from model defined below 231 request-id = SIGNED-INTEGER; whose value is > 0232 233 compound-attribute = attribute \*additional-values 234 235 attribute = value-tag name-length name value-length value 236 237 additional-values = value-tag zero-name-length value-length value 238 name-length = SIGNED-SHORT ; number of octets of 'name' 239 name = LALPHA \*( LALPHA / DIGIT / "-" / "\_" / "." ) 240 value-length = SIGNED-SHORT; number of octets of 'value' 241 value = OCTET-STRING 242 243 data = OCTET-STRING 244 245 zero-name-length = % x00.00 ; name-length of 0 246 operation-attributes-tag = %x01 ; tag of 1 247 job-attributes-tag ; tag of 2 = % x02248 printer-attributes-tag = % x04249 ; tag of 4 unsupported- attributes-tag = %x05 ; tag of 5 250 end-of-attributes-tag = % x03; tag of 3 251 value-tag = %x10-FF252 253 SIGNED-BYTE = BYTE 254 SIGNED-SHORT = 2BYTE 255 SIGNED-INTEGER = 4BYTE 256 257 DIGIT = %x30-39 ; "0" to "9" LALPHA = %x61-7A; "a" to "z" 258 BYTE = %x00-FF259

- The syntax allows an xxx-attributes-tag to be present when the xxx-attribute-sequence that follows is empty. The syntax is 262
- defined this way to allow for the response of Get-Jobs where no attributes are returned for some job-objects. Although it is 263
- RECOMMENDED that the sender not send an xxx-attributes-tag if there are no attributes (except in the Get-Jobs response just 264
- mentioned), the receiver MUST be able to decode such syntax. 265

#### 3.3 Version-number

- The version-number MUST consist of a major and minor version-number, each of which MUST be represented by a SIGNED-267
- BYTE. The protocol described in this document MUST have a major version-number of 1 (0x01) and a minor version-number 268
- of 1 (0x01). The ABNF for these two bytes MUST be %x01.01. 269

#### 3.4 Operation-id 270

- Operation-ids are defined as enums in the model document. An operation-ids enum value MUST be encoded as a SIGNED-271
- SHORT. 272

266

Note: the values 0x4000 to 0xFFFF are reserved for private extensions. 273

#### 3.5 Status-code 274

- Status-codes are defined as enums in the model document. A status-code enum value MUST be encoded as a SIGNED-SHORT. 275
- The status-code is an operation attribute in the model document. In the protocol, the status-code is in a special position, outside 276
- 277 of the operation attributes.
- If an IPP status-code is returned, then the HTTP Status-Code MUST be 200 (successful-ok). With any other HTTP Status-Code 278
- value, the HTTP response MUST NOT contain an IPP message-body, and thus no IPP status-code is returned. 279

#### 3.6 Request-id 280

- The request-id allows a client to match a response with a request. This mechanism is unnecessary in HTTP, but may be useful 281
- when application/ipp entity bodies are used in another context. 282
- The request-id in a response MUST be the value of the request-id received in the corresponding request. A client can set the 283
- 284 request-id in each request to a unique value or a constant value, such as 1, depending on what the client does with the request-
- id returned in the response. The value of the request-id MUST be greater than zero. 285

#### **3.7** Tags 286

288

- There are two kinds of tags: 287
  - delimiter tags: delimit major sections of the protocol, namely attributes and data
- value tags: specify the type of each attribute value 289
- 3.7.1 Delimiter Tags 290
- The following table specifies the values for the delimiter tags: 291

Tag Value (Hex)	Delimiter
0x00	reserved
0x01	operation-attributes-tag
0x02	job-attributes-tag
0x03	end-of-attributes-tag
0x04	printer-attributes-tag
0x05	unsupported-attributes-tag
0x06-0x0e	reserved for future delimiters
0x0F	reserved for future chunking-end-of-attributes-tag

When an xxx-attributes-tag occurs in the protocol, it MUST mean that zero or more following attributes up to the next 292 delimiter tag are attributes belonging to group xxx as defined in the model document, where xxx is operation, job, printer, 293

unsupported. 294

295

296

297

298

299

300

301

302

- Doing substitution for xxx in the above paragraph, this means the following. When an operation-attributes-tag occurs in the protocol, it MUST mean that the zero or more following attributes up to the next delimiter tag are operation attributes as defined in the model document. When an job-attributes-tag occurs in the protocol, it MUST mean that the zero or more following attributes up to the next delimiter tag are job attributes or job template attributes as defined in the model document. When a printer-attributes-tag occurs in the protocol, it MUST mean that the zero or more following attributes up to the next delimiter tag are printer attributes as defined in the model document. When an unsupported-attributes-tag occurs in the protocol, it MUST mean that the zero or more following attributes up to the next delimiter tag are unsupported attributes as defined in the model document.
- 303 The operation-attributes-tag and end-of-attributes-tag MUST each occur exactly once in an operation. The operation-attributes-304 tag MUST be the first tag delimiter, and the end-of-attributes-tag MUST be the last tag delimiter. If the operation has a document-content group, the document data in that group MUST follow the end-of-attributes-tag. 305
- 306 Each of the other three xxx-attributes-tags defined above is OPTIONAL in an operation and each MUST occur at most once in an operation, except for job-attributes-tag in a Get-Jobs response which may occur zero or more times. 307
- The order and presence of delimiter tags for each operation request and each operation response MUST be that defined in the 308 model document. For further details, see section 3.9 "(Attribute) Name" and section 11 "Appendix A: Protocol Examples". 309
- A Printer MUST treat the reserved delimiter tags differently from reserved value tags so that the Printer knows that there is an 310 entire attribute group that it doesn't understand as opposed to a single value that it doesn't understand. 311
- 3.7.2 Value Tags 312
- 313 The remaining tables show values for the value-tag, which is the first octet of an attribute. The value-tag specifies the type of the value of the attribute. The following table specifies the "out-of-band" values for the value-tag. 314

Tag Value (Hex)	Meaning
0x10	unsupported
0x11	reserved for future 'default'
0x12	unknown
0x13	no-value
0x14-0x1F	reserved for future "out-of-band" values.

The "unsupported" value MUST be used in the attribute-sequence of an error response for those attributes which the printer 315 does not support. The "default" value is reserved for future use of setting value back to their default value. The "unknown" 316 value is used for the value of a supported attribute when its value is temporarily unknown. The "no-value" value is used for a 317

- supported attribute to which no value has been assigned, e.g. "job-k-octets-supported" has no value if an implementation supports this attribute, but an administrator has not configured the printer to have a limit.
- 320 The following table specifies the integer values for the value-tag:

Tag Value (Hex)	Meaning	
0x20	reserved	
0x21	integer	
0x22	boolean	
0x23	enum	
0x24-0x2F	reserved for future integer types	

- NOTE: 0x20 is reserved for "generic integer" if it should ever be needed.
- The following table specifies the octetString values for the value-tag:

Tag Value (Hex)	Meaning
0x30	octetString with an unspecified format
0x31	dateTime
0x32	resolution
0x33	rangeOfInteger
0x34	reserved for collection (in the future)
0x35	textWithLanguage
0x36	nameWithLanguage
0x37-0x3F	reserved for future octetString types

323 The following table specifies the character-string values for the value-tag:

Tag Value (Hex)	Meaning
0x40	reserved
0x41	textWithoutLanguage
0x42	nameWithoutLanguage
0x43	reserved
0x44	keyword
0x45	uri
0x46	uriScheme
0x47	charset
0x48	naturalLanguage
0x49	mimeMediaType
0x4A-0x5F	reserved for future character string types

- NOTE: 0x40 is reserved for "generic character-string" if it should ever be needed.
- NOTE: an attribute value always has a type, which is explicitly specified by its tag; one such tag value is
- "nameWithoutLanguage". An attribute's name has an implicit type, which is keyword.
- The values 0x60-0xFF are reserved for future types. There are no values allocated for private extensions. A new type MUST be
- registered via the type 2 registration process [ipp-mod].
- The tag 0x7F is reserved for extending types beyond the 255 values available with a single byte. A tag value of 0x7F MUST

signify that the first 4 bytes of the value field are interpreted as the tag value. Note, this future extension doesn't affect parsers

- that are unaware of this special tag. The tag is like any other unknown tag, and the value length specifies the length of a value
- which contains a value that the parser treats atomically. All these 4 byte tag values are currently unallocated except that the
- values 0x40000000-0x7FFFFFFF are reserved for experimental use.

### 3.8 Name-Length

334

340

343

344

345

346

347

348

349

350

363

364

365

366

367

368

369

370 371

- The name-length field MUST consist of a SIGNED-SHORT. This field MUST specify the number of octets in the name field which follows the name-length field, excluding the two bytes of the name-length field.
- If a name-length field has a value of zero, the following name field MUST be empty, and the following value MUST be treated
- as an additional value for the preceding attribute. Within an attribute-sequence, if two attributes have the same name, the first
- occurrence MUST be ignored. The zero-length name is the only mechanism for multi-valued attributes.

#### 3.9 (Attribute) Name

- Some operation elements are called parameters in the model document [ipp-mod]. They MUST be encoded in a special position and they MUST NOT appear as an operation attributes. These parameters are:
  - "version-number": The parameter named "version-number" in the IPP model document MUST become the "version-number" field in the operation layer request or response.
  - "operation-id": The parameter named "operation-id" in the IPP model document MUST become the "operation-id" field in the operation layer request.
  - "status-code": The parameter named "status-code" in the IPP model document MUST become the "status-code" field in the operation layer response.
  - "request-id": The parameter named "request-id" in the IPP model document MUST become the "request-id" field in the operation layer request or response.
- All Printer and Job objects are identified by a Uniform Resource Identifier (URI) [rfc2396] so that they can be persistently and unambiguously referenced. The notion of a URI is a useful concept, however, until the notion of URI is more stable (i.e.,
- defined more completely and deployed more widely), it is expected that the URIs used for IPP objects will actually be URLs
- 354 [rfc1738] [rfc1808]. Since every URL is a specialized form of a URI, even though the more generic term URI is used
- 355 throughout the rest of this document, its usage is intended to cover the more specific notion of URL as well.
- 356 Some operation elements are encoded twice, once as the request-URI on the HTTP Request-Line and a second time as a
- REQUIRED operation attribute in the application/ipp entity. These attributes are the target URI for the operation and are
- 358 called printer-uri and job-uri. Note: The target URI is included twice in an operation referencing the same IPP object, but the
- 359 two URIs NEED NOT be literally identical. One can be a relative URI and the other can be an absolute URI. HTTP/1.1 allows
- clients to generate and send a relative URI rather than an absolute URI. A relative URI identifies a resource with the scope of
- 361 the HTTP server, but does not include scheme, host or port. The following statements characterize how URLs should be used
- in the mapping of IPP onto HTTP/1.1:
  - 1. Although potentially redundant, a client MUST supply the target of the operation both as an operation attribute and as a URI at the HTTP layer. The rationale for this decision is to maintain a consistent set of rules for mapping application/ipp to possibly many communication layers, even where URLs are not used as the addressing mechanism in the transport layer.
  - 2. Even though these two URLs might not be literally identical (one being relative and the other being absolute), they MUST both reference the same IPP object.
  - 3. The URI in the HTTP layer is either relative or absolute and is used by the HTTP server to route the HTTP request to the correct resource relative to that HTTP server. The HTTP server need not be aware of the URI within the operation request.

373

374

375

380

384

394

- 4. Once the HTTP server resource begins to process the HTTP request, it might get the reference to the appropriate IPP Printer object from either the HTTP URI (using to the context of the HTTP server for relative URLs) or from the URI within the operation request; the choice is up to the implementation.
  - 5. HTTP URIs can be relative or absolute, but the target URI in the operation MUST be an absolute URI.

376 The model document arranges the remaining attributes into groups for each operation request and response. Each such group

MUST be represented in the protocol by an xxx-attribute-sequence preceded by the appropriate xxx-attributes-tag (See the table 377

below and section 11 "Appendix A: Protocol Examples"). In addition, the order of these xxx-attributes-tags and xxx-attribute-378

379 sequences in the protocol MUST be the same as in the model document, but the order of attributes within each xxx-attribute-

sequence MUST be unspecified. The table below maps the model document group name to xxx-attributes-sequence:

#### **Model Document Group**

#### xxx-attributes-sequence

**Operation Attributes** operations-attributes-sequence Job Template Attributes job-attributes-sequence Job Object Attributes job-attributes-sequence **Unsupported Attributes** unsupported- attributes-sequence Requested Attributes (Get-Job-Attributes) job-attributes-sequence

Requested Attributes (Get-Printer-Attributes) printer-attributes-sequence

**Document Content** in a special position as described above

- If an operation contains attributes from more than one job object (e.g. Get-Jobs response), the attributes from each job object 381
- MUST be in a separate job-attribute-sequence, such that the attributes from the ith job object are in the ith job-attribute-382
- sequence. See Section 11 "Appendix A: Protocol Examples" for table showing the application of the rules above. 383

### 3.10 Value Length

- Each attribute value MUST be preceded by a SIGNED-SHORT, which MUST specify the number of octets in the value which 385 follows this length, exclusive of the two bytes specifying the length. 386
- For any of the types represented by binary signed integers, the sender MUST encode the value in exactly four octets. 387
- For any of the types represented by character-strings, the sender MUST encode the value with all the characters of the string 388 and without any padding characters. 389
- If a value-tag contains an "out-of-band" value, such as "unsupported", the value-length MUST be 0 and the value empty the 390
- value has no meaning when the value-tag has an "out-of-band" value. If a client receives a response with a nonzero value-391
- length in this case, it MUST ignore the value field. If a printer receives a request with a nonzero value-length in this case, it 392
- MUST reject the request. 393

#### 3.11 (Attribute) Value

- The syntax types and most of the details of their representation are defined in the IPP model document. The table below 395
- augments the information in the model document, and defines the syntax types from the model document in terms of the 5 396
- basic types defined in section 3 "Encoding of the Operation Layer". The 5 types are US-ASCII-STRING, LOCALIZED-397
- STRING, SIGNED-INTEGER, SIGNED-SHORT, SIGNED-BYTE, and OCTET-STRING. 398

#### Syntax of Attribute Value

### **Encoding**

textWithoutLanguage, nameWithoutLanguage LOCALIZED-STRING.

Syntax of Attribute Value	Encoding
textWithLanguage	OCTET_STRING consisting of 4 fields:  a) a SIGNED-SHORT which is the number of octets in the following field b) a value of type natural-language, c) a SIGNED-SHORT which is the number of octets in the following field, d) a value of type textWithoutLanguage.  The length of a textWithLanguage value MUST be 4 + the value of field a + the value of field c.
nameWithLanguage	OCTET_STRING consisting of 4 fields:  a) a SIGNED-SHORT which is the number of octets in the following field b) a value of type natural-language, c) a SIGNED-SHORT which is the number of octets in the following field d) a value of type nameWithoutLanguage.  The length of a nameWithLanguage value MUST be 4 + the value of field a + the value of field c.
charset, naturalLanguage, mimeMediaType, keyword, uri, and uriScheme	US-ASCII-STRING.
boolean	SIGNED-BYTE where 0x00 is 'false' and 0x01 is 'true'.
integer and enum	a SIGNED-INTEGER.
dateTime	OCTET-STRING consisting of eleven octets whose contents are defined by "DateAndTime" in RFC 1903 [rfc1903].
resolution	OCTET_STRING consisting of nine octets of 2 SIGNED-INTEGERs followed by a SIGNED-BYTE. The first SIGNED-INTEGER contains the value of cross feed direction resolution. The second SIGNED-INTEGER contains the value of feed direction resolution. The SIGNED-BYTE contains the units value.
rangeOfInteger	Eight octets consisting of 2 SIGNED-INTEGERs. The first SIGNED-INTEGER contains the lower bound and the second SIGNED-INTEGER contains the upper bound.
1setOf X	Encoding according to the rules for an attribute with more than 1 value. Each value X is encoded according to the rules for encoding its type.
octetString	OCTET-STRING

The type of the value in the model document determines the encoding in the value and the value of the value-tag.

## 400 **3.12 Data**

The data part MUST include any data required by the operation

## 4. IPP URL Scheme

IPP/1.1 uses a new scheme 'ipp' as the value of a URL that identifies either an IPP printer object or an IPP job object. The IPP 403 attributes using the 'ipp' scheme are specified below. Because the HTTP layer does not support the 'ipp' scheme, a client 404 MUST map 'ipp' URLs to 'http' URLs, and then follows the HTTP [RFC2068][RFC2069] rules for constructing a Request-Line 405 and HTTP headers. The mapping is simple because the 'ipp' scheme implies all of the same protocol semantics as that of the 406 'http' scheme [RFC2068], except that it represents a print service and the implicit (default) port number that clients use to 407

408 connect to a server is port 631.

In the remainder of this section the term 'ipp-URL' means a URL whose scheme is 'ipp' and whose implicit (default) port is 409 631. The term 'http-URL' means a URL whose scheme is 'http', and the term 'https-URL' means a URL whose scheme is 410 'https', 411

A client and an IPP object (i.e. the server) MUST support the ipp-URL value in the following IPP attributes.

```
413
          job attributes:
414
                      job-uri
                      job-printer-uri
415
           printer attributes:
416
417
                      printer-uri-supported
           operation attributes:
418
                      job-uri
419
                      printer-uri
```

420 421 422

423

412

402

Each of the above attributes identifies a printer or job object. The ipp-URL is intended as the value of the attributes in this list, and for no other attributes. All of these attributes have a syntax type of 'uri', but there are attributes with a syntax type of 'uri' that do not use the 'ipp' scheme, e.g. 'job-more-info'.

424 425 426

If a printer registers its URL with a directory service, the printer MUST register an ipp-URL.

User interfaces are beyond the scope of this document. But if software exposes the ipp-URL values of any of the above five attributes to a human user, it is REQUIRED that the human see the ipp-URL as is.

428 429 430

431

432

433 434

427

When a client sends a request, it MUST convert a target ipp-URL to a target http-URL for the HTTP layer according to the following rules:

- 1. change the 'ipp' scheme to 'http'
  - 2. add an explicit port 631 if the URL does not contain an explicit port. Note: port 631 is the IANA assigned Well Known Port

The client MUST use the target http-URL in both the HTTP Request-Line and HTTP headers, as specified by 435 HTTP[RFC2068][RFC2069]. However, the client MUST use the target ipp-URL for the value of the "printer-uri" or "job-uri" 436 437 operation attribute within the application/ipp body of the request. The server MUST use the ipp-URL for the value of the "printer-uri", "job-uri" or "printer-uri-supported" attributes within the application/ipp body of the response. 438

439

For example, when an IPP client sends a request directly (i.e. no proxy) to an ipp-URL 440

"ipp://myhost.com/myprinter/myqueue", it opens a TCP connection to port 631 (the ipp implicit port) on the host 441 "myhost.com" and sends the following data: 442

443

```
POST /myprinter/myqueue HTTP/1.1
444
```

Host: myhost.com:631 445 Content-type: application/ipp 446 Transfer-Encoding: chunked 447 448

"printer-uri" "ipp://myhost.com/myprinter/myqueue" 449

465

466

469

470

471

478

481

482

483

484

485

486

487

488 489

(encoded in application/ipp message body) 450 451 452 As another example, when an IPP client sends the same request as above via a proxy "myproxy.com", it opens a TCP 453 connection to the proxy port 8080 on the proxy host "myproxy.com" and sends the following data: 454 455 POST http://myhost.com:631/myprinter/myqueue HTTP/1.1 456 Host: myhost.com:631 457 458 Content-type: application/ipp Transfer-Encoding: chunked 459 460 "printer-uri" "ipp://myhost.com/myprinter/myqueue" 461 (encoded in application/ipp message body) 462 463

The proxy then connects to the IPP origin server with headers that are the same as the "no-proxy" example above.

# 5. Encoding of Transport Layer

- 467 HTTP/1.1 [rfc2068] is the transport layer for this protocol.
- The operation layer has been designed with the assumption that the transport layer contains the following information:
  - the URI of the target job or printer operation
  - the total length of the data in the operation layer, either as a single length or as a sequence of chunks each with a length.

It is REQUIRED that a printer implementation support HTTP over the IANA assigned Well Known Port 631 (the IPP default port), though a printer implementation may support HTTP over some other port as wellAn IPP server sends a response for each request that it receives. If an IPP server detects an error, it MAY send a response before it has read the entire request. If the HTTP layer of the IPP server completes processing the HTTP headers successfully, it MAY send an intermediate response, such as "100 Continue", with no IPP data before sending the IPP response. A client MUST expect such a variety of responses from an IPP server. For further information on HTTP/1.1, consult the HTTP documents [rfc2068].

# 6. Compatibility with IPP/1.0

- IPP 1.1 must be compatible with IPP 1.0, as defined in [ipp-mod-10] and [ipp-pro-10] documents. For compatibility with IPP/1.0, clients and IPP objects (i.e. a server) MUST support additional schemes as described in this section:
  - ? If a server receives an IPP/1.0 request, it MUST return an IPP/1.0 response. That is, it MUST support both an http-URL and an https-URL in the target "printer-uri" and "job-uri" operation attributes in a request. The rules for attributes in a response is covered in the next two bullet items.
  - ? When a server returns the printer attribute "printer-uri-supported", it MUST return all values of the attribute for an IPP/1.1 request. For an IPP/1.0 request, a server MUST return a subset of the attribute values, excluding those that are ipp-URLs, and including those that are http-URLs and https-URLs..
  - ? The table below shows the type of URL that a server returns for the "job-uri" and "job-printer-uri" job attributes for all operations based on how the job was created. The "or" in the table below indicates an implementation option.

Operation attributes for a	Job created via			
request	ipp	secure ipp	http	https
ipp	ipp	No URL returned	ipp	No URL returned
secure ipp	ipp	ipp	ipp	ipp
http	http	No URL returned	http	No URL returned
https	https or http	https	https or http	https

491

492

? If a server registers a nonsecure ipp-URL with a name service, then it MUST also register an http-URL. If a printer supports a secure connection using SSL3, then it MUST register an https-URL.

493 494 495 An IPP/1.1 client MUST use an ipp-URL for non-secure printers unless it receives a "version not supported" error message. Then it MUST try to send a request in version 1.0, using the http-URL in place of the ipp-URL for the target "job-uri" and "printer-uri" operation attributes in the request. For secure printers, an IPP/1.1 client must use the HTTP "Upgrade: TLS/1.0" header (see section 7). An IPP/1.0 client MUST use an http-URL for non-secure printers and an https-URL for secure printers.

497 498

499

500

501

502

503

504 505

506

507

496

Note: even though port 631 is the IPP default, port 80 remains the default for an HTTP URL. Thus an HTTP URL for a printer using port 631 MUST contain an explicit port, e.g. "http://forest:631/pinetree". An HTTP URL for IPP with no explicit port implicitly references port 80, which is consistent with the rules for HTTP/1.1. Each HTTP operation MUST use the POST method where the request-URI is the object target of the operation, and where the "Content-Type" of the message-body in each request and response MUST be "application/ipp". The message-body MUST contain the operation layer and MUST have the syntax described in section 3.2 "Syntax of Encoding". A client implementation MUST adhere to the rules for a client described for HTTP1.1 [rfc2068]. A printer (server) implementation MUST adhere the rules for an origin server described for HTTP1.1 [rfc2068].

# 7. Security Considerations

The IPP Model document defines an IPP implementation with "privacy" as one that implements Transport Layer Security (TLS) [rfc2246]. TLS meets the requirements for IPP security with regards to features such as mutual authentication and privacy (via encryption). The IPP Model document also outlines IPP-specific security considerations and should be the primary

reference for security implications with regards to the IPP protocol itself.

The IPP Model document defines an IPP implementation with "authentication" as one that implements the standard way for transporting IPP messages within HTTP 1.1. These include the security considerations outlined in the HTTP 1.1 standard document [rfc2068] and Digest Access Authentication extension [rfc2069].

The current HTTP infrastructure supports HTTP over TCP port 80. IPP server implementations MUST offer IPP services using HTTP over the IANA assigned Well Known Port 631 (the IPP default port). IPP server implementations may support other

517 ports, in addition to this port.

See further discussion of IPP security concepts in the model document [ipp-mod].

#### 7.1 Using IPP with TLS

- An initial IPP request never uses TLS. The switch to TLS occurs either because the server grants the client's request to
- 521 upgrade to TLS, or a server asks to switch to TLS in its response. Secure communication begins with a server's response to
- switch to TLS. During the TLS handshake, the original session is preserved.
- An IPP client that wants a secure connection MUST send "TLS/1.0" as one of the field-values of the Upgrade request header,
- e.g. "Upgrade: TLS/1.0" (see rfc2068 section 14.42). If the origin-server grants the upgrade request, it MUST respond with
- 525 "101 Switching Protocols", and it MUST include the header "Upgrade: TLS/1.0" to indicate what it is switching to. An IPP
- 526 client MUST be ready to react appropriately if the server does not grant the upgrade request. Note: the 'Upgrade header'
- mechanism allows unsecured and secured traffic to share the same port (in this case, 631).
- With current technology, an IPP server can indicate that it wants an upgrade only by returning "401 unauthorized" or "403
- forbidden". A server MAY give the client an additional hint by including an "Upgrade: TLS" header in the response. When an
- IPP client receives such a response, it can perform the request again with an Upgrade header with the "TLS/1.0" value.
- 531 If a server supports TLS, it SHOULD include the "Upgrade" header with the value "TLS/1.0" in response to any OPTIONS
- 532 request.

519

- 533 Upgrade is a hop-by-hop header (rfc2068, section 13.5.1), so each intervening proxy which supports TLS MUST also request
- the same version of TLS/1.0 on its subsequent request. Furthermore, any caching proxy which supports TLS MUST NOT reply
- from its cache when TLS/1.0 has been requested (although clients are still recommended to explicitly include "Cache-control:
- 536 no-cache").

542

- Note: proxy servers may be able to request or initiate a TLS-secured connection, e.g. the outgoing or incoming firewall of a
- 538 trusted subnetwork.
- Note: the initial connection (containing the Upgrade header) is not secure. Any client expecting a secure connection should
- first use a non-sensitive operation (e.g. an HTTP POST with an empty message body) to establish a secure connection before
- sending any sensitive data.

## 11.3 Print-Job Response (failure)

Here is an example of an unsuccessful Print-Job response to the previous Print-Job request. It fails because, in this case, the printer does not support the "sides" attribute and because the value '20' for the "copies" attribute is not supported. Therefore, no job is created, and neither a "job-id" nor a "job-uri" operation attribute is returned. The error code returned is 'client-error-attributes-or-values-not-supported' (0x040B).

Octets	Symbolic Value	Protocol field

### 11.4 Print-Job Response (success with attributes ignored)

Here is an example of a successful Print-Job response to a Print-Job request like the previous Print-Job request, except that the value of 'ipp-attribute-fidelity' is false. The print request succeeds, even though, in this case, the printer supports neither the "sides" attribute nor the value '20' for the "copies" attribute. Therefore, a job is created, and both a "job-id" and a "job-uri" operation attribute are returned. The unsupported attributes are also returned in an Unsupported Attributes Group. The error code returned is 'successful-ok-ignored-or-substituted-attributes' (0x0001).

# 12. Appendix C: Registration of MIME Media Type Information for "application/ipp"

- This appendix contains the information that IANA requires for registering a MIME media type. The information following this paragraph will be forwarded to IANA to register application/ipp whose contents are defined in Section 3 "Encoding of the
- Operation Layer" in this document:
- 624 **MIME type name:** application
- 625 MIME subtype name: ipp
- 626 A Content-Type of "application/ipp" indicates an Internet Printing Protocol message body (request or response). Currently there
- is one version: IPP/1.1, whose syntax is described in Section 3 "Encoding of the Operation Layer" of [ipp-pro], and whose
- semantics are described in [ipp-mod].
- 629 Required parameters: none
- 630 **Optional parameters:** none
- 631 Encoding considerations:
- 632 IPP/1.1 protocol requests/responses MAY contain long lines and ALWAYS contain binary data (for example attribute value
- 633 lengths).

638

619

620

- 634 Security considerations:
- 635 IPP/1.1 protocol requests/responses do not introduce any security risks not already inherent in the underlying transport
- 636 protocols. Protocol mixed-version interworking rules in [ipp-mod] as well as protocol encoding rules in [ipp-pro] are complete
- and unambiguous.
  - **Interoperability considerations:**
- 639 IPP/1.1 requests (generated by clients) and responses (generated by servers) MUST comply with all conformance requirements
- imposed by the normative specifications [ipp-mod] and [ipp-pro]. Protocol encoding rules specified in [ipp-pro] are
- comprehensive, so that interoperability between conforming implementations is guaranteed (although support for specific
- optional features is not ensured). Both the "charset" and "natural-language" of all IPP/1.1 attribute values which are a

- 643 LOCALIZED-STRING are explicit within IPP protocol requests/responses (without recourse to any external information in 644 HTTP, SMTP, or other message transport headers).
- 645 **Published specification:**
- [ipp-mod] Isaacson, S., deBry, R., Hastings, T., Herriot, R., Powell, P., "Internet Printing Protocol/1.1: Model and

Semantics" draft-ietf-ipp-mod-v11-00.txt, February, 1999.

[ipp-pro] Herriot, R., Butler, S., Moore, P., Turner, R., "Internet Printing Protocol/1.1: Encoding and Transport", draft-ietf-

ipp-protocol-v11-00.txt, February, 1999.

- 650 Applications which use this media type:
- 651 Internet Printing Protocol (IPP) print clients and print servers, communicating using HTTP/1.1 (see [IPP-PRO]),
- 652 SMTP/ESMTP, FTP, or other transport protocol. Messages of type "application/ipp" are self-contained and transport-
- 653 independent, including "charset" and "natural-language" context for any LOCALIZED-STRING value.

- 696 PARTICULAR PURPOSE.

# 14. Appendix E: Changes from IPP /1.0

- 698 IPP/1.1 is identical to IPP/1.0 with the follow changes:
- 699 1. Attributes values that identify a printer or job object use a new 'ipp' scheme. The 'http' and 'https' schemes are supported only for backward compatibility.
- 701 2. TLS provides security. SSL3 is supported only for backward compatibility.
